[A]
Sequential Retain-and-Enter Model
Simulation conditions:
active actor set, budgets K_{at}, and pooled Φ are fixed;
a scalar intercept shift calibrates support levels.
1. Retain Prior Topics
Keep topics already in the portfolio.
Retention is stronger for previously important topics.
Uses prior topic weight $s_{ai,t-1}$
$\lambda_{ret} = 0.42$
2. Enter Nearby Topics
Add topics that sit near the prior support in the pooled concern space Φ.
Local fit = mean $\phi(i,j)$ to previously held topics.
New topics are more likely if they are close to the prior support.
$\beta_{ent} = 0.58$
3. Allocate Budget
Condition on observed active actors and observed budgets K_{at}.
Allocate within the selected support.
Uses prior shares and local fit.
$\rho = 4.29$, $\beta = 3.97$
[B] Mean Active Topics Per Actor
Observed mean = 3.35
Split model = 3.32
r = 0.872
Band = 5--95% over 64 runs
Topics
Year
[C] Mean Topic Popularity
Observed mean = 2.45
Split model = 2.45
r = 0.977
Band = 5--95% over 64 runs
Active actors per topic
Year
[D] Local Entry In Φ-Space
Observed = 0.677
Split model = 0.675
5--95% = [0.662, 0.688]
Mean rank of entered topics
