

[A]

Sequential Retain-and-Enter Model

1. Retain Prior Topics

Keep topics already in the portfolio.
Retention is stronger for previously important topics.

Uses prior topic weight $s_{ai, t-1}$

$$\lambda_{ret} = 0.42$$

2. Enter Nearby Topics

Add topics that sit near the prior support in the pooled concern space Φ .

Local fit = mean $\phi(i, j)$ to previously held topics.

New topics are more likely if they are close to the prior support.

$$\beta_{ent} = 0.58$$

3. Allocate Budget

Condition on observed active actors and observed budgets K_{at} .

Allocate within the selected support. Uses prior shares and local fit.

$$\rho = 4.29, \beta = 3.97$$

Simulation conditions:
active actor set, budgets K_{at} , and pooled Φ are fixed;
a scalar intercept shift calibrates support levels.
